EXECUTIVE SUMMARY

The goal of this study was to determine sizing recommendations to improve the fit of the MBU-20/P Advanced Aircrew Oxygen Mask (AAOM). Quality of fit is related to factors such as anthropometry, performance, and personal preference. Performance must be considered, because the quality of fit can change with usage. A mask with a good seal on the ground may break seal at high g. This is not an acceptable fit, so the size of the mask must be modified. Furthermore, some people are more tolerant of discomfort than others. A mask designed for two people with the same facial anatomy may be tolerable to one person and uncomfortable to another. An uncomfortable mask is a safety risk, so its size must be modified. What do you do when your suit doesn't fit? You take it to a tailor to have its size altered. Essentially, you have conducted your own fit test and have determined that the size is not right. When we see a lot of the same problems with fit, it is natural to want to know why the problem is there and what to do to fix it. Understanding the relationship of anthropometry to an acceptable quality of fit is key to making recommendations reqarding sizing. Fit testing is a method commonly used to take anthropometry, performance, and personal preference into account when making sizing recommendations. As such, our approach was to do a fit test of the AAOM mask using the current sizes and analyze the difference between subjects who passed the fit test and those who failed.

Thirty male and thirty female subjects were tested. The subjects were fit into the proper size by an expert fitter who evaluated the initial fit. After this they were measured and the fit of the mask was assessed. Twenty of the male subjects were from an active duty unit at Luke AFB. These subjects were fit tested after flying with the mask. The remaining men and all of the women were provided by AL/CFT at Brooks AFB. This location was selected with the intent that all subjects could be fit tested after having either flown or been taken to a high-G level on the centrifuge. Most of the male test subjects provided were fit tested after having been exposed to high-G. Unfortunately, only two female test subjects were provided that had ridden the centrifuge, and none had flight experience with the mask.

The results for both sexes indicate that Sellion to Supramenton Length distinguishes between sizes. This is to be expected as it is the size selection measurement used in the technical order (TO). The results for the males further indicate that the primary factor for quality of fit within a size is the placement of the mask on the face. There was evidence for this in all sizes. Furthermore, there were no statistically detectable differences in facial anatomy within a size between subjects who passed and those who failed.

While no anatomical differences were found, that does not mean they do not exist. It merely indicates two things: the scale of the effect due to placement was large in comparison to any possible anatomical effects and/or the fit data do not correlate well to the mask to face interface extracted from the scan. In either case, if there are any anatomical differences, they were undetectable. These conclusions were further supported by testing done by AL/CFT to compare sizes MN and MW. In that test all subjects who were re-tested in the same size changed overall fit score. In other words, when the same mask was put on a second time they got a different fit rating. A method was devised to help pilots ensure that they replace the mask in the proper position during routine use.

If anatomical differences are merely hidden by the other fit factors, we have no statistically significant evidence to describe them. Having no evidence for new sizes, anecdotal information from expert fitters was relied upon to make a judgment about the regions where new masks might be needed. Simple proportional growth differences between existing sizes was used to scale the three-dimensional changes needed to proportion the two new sizes. The old sizes were scanned and three-dimensional representations are available. The next step would be to create computer models of the new sizes. It is recommended that these new sizes also be tested.

INTRODUCTION

The goal of this study was to determine sizing recommendations to improve the fit of the MBU-20/P Advanced Aircrew Oxygen Mask (AAOM). The approach was to do a fit test of the mask using the current sizes and analyze the differences between subjects who passed and those who failed. This was done in conjunction with an effort to develop a customization process method for the soft rubber portion of the mask. It has two basic pieces which affect fit, a hard shell and a soft rubber insert (face piece). The sizes currently available are SN (Small Narrow), MN (Medium Narrow), MW (Medium Wide), and LW (Large Wide). This sizing study concentrates on the hard shell.

METHODS

Anthropometry and fit data were collected from 30 male and 30 female subjects. The data was collected at Luke Air Force Base (Phoenix, AZ), 7 through 15 December, 1994, and at Brooks Air Force Base (San Antonio, TX), 31 January through 8 February, 1995. All of the female data came from the Brooks survey, while 20 of the male subjects came from the Luke survey and the remaining 10 males from the Brooks survey.

DATA COLLECTION

The overall data collection method is summarized in Figure 1 on the following page. First, the mask was fit by an expert fitter using the appropriate technical order (TO 14P3-1-161). The fit of the mask was verified by the fitter with the TTU/529-E tester using the appropriate technical order (TO 33D2-10-68-1). Adjustments to the strap lengths were made by the fitter until the subject was able to seal on the tester. For subjects not obtaining a seal on the tester, the fitter either ground the hard shell of the MBU-20/P mask or tried a neighboring size. The fit of the mask was again verified with the tester, and appropriate adjustments to the strap lengths were made. This fitting process was repeated until the fitter was confident that the subject had an acceptable fit in the mask. At this point the fitter completed the "COMBAT EDGE MASK GRINDING CHECKLIST" shown in Appendix A.

The next step in the process occurred along two parallel paths. Ideally, all subjects would have tested the fit of the mask in an operational fighter aircraft or a centrifuge. This was not possible, especially for the female subjects. Therefore, some subjects had no testing of the mask in an aircraft or centrifuge and did not experience accelerations above 1 G with the mask. The fit for subjects that did test the mask on an aircraft or centrifuge was then re-evaluated by an expert fitter. If the subject obtained an unacceptable fit with this operational testing, the subject recycled back to the fitter for strap readjustments, grinding of the hard shell, or trying a neighboring size. Those subjects that obtained an acceptable fit then reported to the Armstrong Laboratory Team for fit testing and anthropometric data collection. At this point, subjects should have had the best possible fit with the MBU-20/P oxygen mask.

The Armstrong Lab Team first briefed the subject regarding the remainder of the data collection steps. The briefing included obtaining informed consent from the subject. (The consent form used, "Protocol 83-30," is included in Appendix B.) Next, the subject was interviewed regarding the fit of their mask. The interview was structured around completion of a fit assessment questionnaire (included as Appendix C). Using the form, detailed information regarding fit in terms of comfort, slippage, and leaks was obtained. In addition, data was collected regarding the number of sorties or centrifuge runs the subject had completed with the mask and whether or not positive pressure breathing was used at G. Helmet size, mask size, and whether or not the mask had been ground was also recorded.

AAOM DATA COLLECTION FLOW

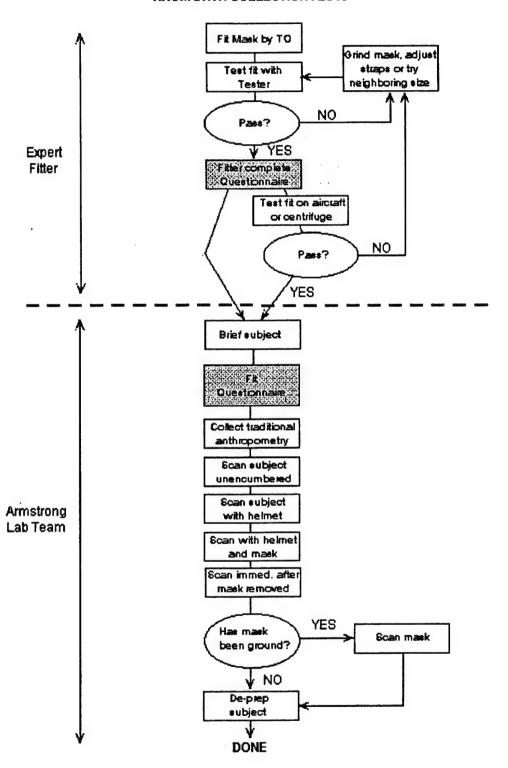

Figure 1. AAOM Data Collection Flow

Next, traditional anthropometric data were collected on each subject. The form "AAOM ANTHROPOMETRY" (Appendix D) was filled out to record the subject's traditional anthropometric measurements. Basic demographic data were also collected using this form. Subjects were first marked with 16 landmarks, as shown in Figure 2, with round, 1/4 inch, light blue, gummed-back stickers. Calipers and a steel tape measure were then used to collect 15 measurements prior to placement of a smooth, thin, rubber cap over the subject's hair. The cap was used to more accurately represent head shape during the scanning procedure. Three measurements were also taken after cap placement. Descriptions of the landmarks and measurements can be found in Appendices E and F, "Anatomical and Auxilliary Landmark Descriptions" and "Definitions of AAOM Anthropometry."

The next steps included scanning of the subject with a Cyberware 4020 RGB/PS-D Color 3-D Digitizer. The digitizer uses a laser and two cameras to record up to 130,000 points spaced approximately 1.5 mm apart on the surface of the subject's head and shoulders in approximately 17 seconds. The scanner records the location of each point in three-dimensional space, along with the color of the surface at each point. Four scans were obtained from all subjects, and a fifth scan was obtained from subjects with ground masks.

With the exception of the thin, rubber cap mentioned earlier, the subject was unencumbered (i.e., the subject was not wearing any life support equipment) for the first scan. The cap was removed for subsequent scans, but the blue stickers on the landmarks were present for all scans.

Next, the subject was scanned while wearing an appropriately fit HGU-55/P helmet. Three blue stickers were also placed on the helmet for subsequent data analysis.

For the third scan, the subject put their mask on as the expert fitter had instructed them to do. This represented how they would have worn the mask operationally. To facilitate data analysis, six blue stickers were placed on all masks, and a thin yellow piece of tape was placed on the ground edge of any mask that had been ground. The blue stickers were surrounded by a white, gummed back sticker with a 1/4 inch inner diameter and 9/16 inch outer diameter to increase the contrast between the blue stickers and the mask. The placement of the stickers can be seen in Figure 2.

The fourth scan was obtained within 30 seconds of removal of the mask, and without taking off the helmet. This scan was taken to secondarily record the mask placement by capturing the location of the red line (from reactive hyperemia) on the subject's face where the mask had been seated.

If the subject had a mask that had been ground, a fifth scan of the mask alone was made. In this scan, the mask was positioned so that the scanner would optimally record the shape of the ground surface.

Finally, the subject was debriefed regarding the study, and all blue stickers were removed.

SAMPLE SELECTION

After data was collected on a sample of 20 males at Luke Air Force Base, the sample was examined for gaps in the expected distribution. We compared the Luke sample to the 1967 Air Force Males, the 1990 Air Force Male Flyers, and the 1988 Army Males based on Face Length (Menton-Sellion Length) and Face Breadth (Bizygomatic Breadth). We used these comparisons to determine the dimensions and number of subjects we needed to sample at Brooks. Figures G1, G2, and G3 of Appendix G illustrate these comparisons indicating the sample actually collected at Brooks and Luke, as well as the number of subjects (within each box) we *intended* to sample at Brooks.

Since no female data were gathered at Luke, we prepared a sampling strategy before female data collection began at Brooks. The 1968 Air Force Females and a subset of women from that dataset who

Figure 2. Palpated Landmarks

met pilot training entry requirements were examined (Figures G4 and G5 of Appendix G). The numbers inside the grid represent the number of women within each box that we intended to sample at Brooks.

The sampling strategy was based on an estimation of the percentage of subjects that fall within the "gaps" and an educated guess on the amount of data required to make sound conclusions. The figures show that we did not obtain the desired samples for men or women. The female sample is particularly void of women with smaller faces.

DATA PREPARATION

Before analysis of the three-dimensional surface scan data could begin, landmark locations (both anatomical and equipment-based) had to be digitized. Integrate, the CARD Laboratory's 3-D visualization, manipulation and analysis software (Burnsides, et al., 1995); was used to load each of the subjects' scans one at a time. Any voids in a data set were first filled by an interpolation routine. Voids are normally caused by a lack of reflection of the laser light from the scanned surface (e.g. due to extremely dark colors or a portion of the surface that is nearly tangential to the laser). Landmarks were then digitized by using a mouse to place the cursor over the center of the landmark, and then pressing the left mouse button. Once all landmarks of interest were digitized, the landmarks' three-dimensional coordinate locations were saved (cylindrical and cartesian) in a separate landmark file.

IDENTIFYING THE MASK TO FACE INTERFACE

Because shape information was viewed as a likely candidate for identifying fit differences, it was important to identify the location on each subject where the mask seal met the face. Locating this seal area required several steps of data manipulation. The first step was to load a scan of the appropriate size face piece into Integrate. Although scan data for the face piece was used in this step (as opposed to scan data from the hard shell), the two components are nearly identical in size and shape. Landmarks on the mask were used to align the mask into a standard position, hereafter referred to as the mask-axis system (Figure 3). The mask-axis system was defined as follows: The X-axis runs through the lower two landmarks on the front of the hardshell with the origin falling half-way between; the Y-axis is orthogonal to the X-axis and runs through the point half-way between the upper two hardshell landmarks; while the Z-axis is orthogonal to both the X and Y axes. In order to make comparisons between subjects, all scans had to be aligned into a common coordinate system: in this case, the mask-axis system. Scans of one encumbered subject at a time were loaded into Integrate and registered with the face piece (Figure 4). This was performed by finding the least-squares fit of landmarks in common to both datasets. The next step was to load the unencumbered subject's scan and register it with the encumbered scan using the same least-squares technique (Figure 5). Finally, the encumbered scan was deleted, leaving the unencumbered scan aligned with the face piece in the same position as the subject actually wore his mask (Figure 6).

In several cases, the least-squares registration routine did not work as described above. It was theorized that landmarks chosen on the masks were co-planar. Due to software restraints in Integrate, these landmarks could not be registered with another set of similar co-planar landmarks (it is best to define registration landmarks that clearly define three dimensions in order to fix any necessary data rotations and translations during the registration process). This difficulty was overcome by adding an extra step into the registration procedure. In order to "fool" the software into performing the necessary registrations, a different size mask was first registered with the correct size mask, followed by registration of the encumbered subject with the different size mask. The incorrect size mask was then deleted, leaving the correct registration between the encumbered subject and the correct size mask (this is a valid registration since the landmarks on the encumbered subject and those on the correct size mask are located in identical places). The scan of the unencumbered subject was then loaded and registered in the same manner described above.

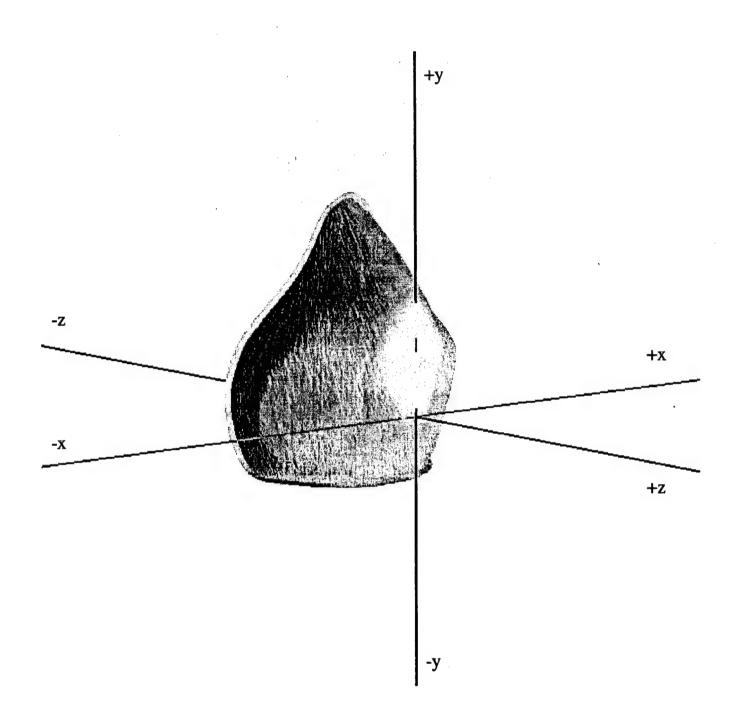

Figure 3. Mask - Axis System

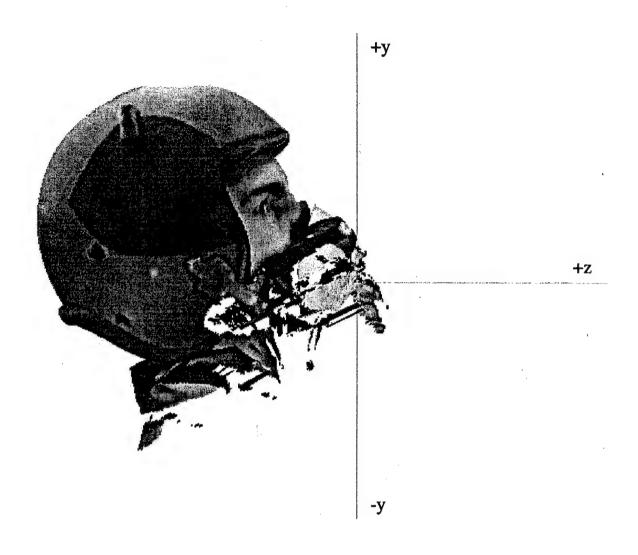

Figure 4. Encumbered Subject Registered with Mask (face piece)

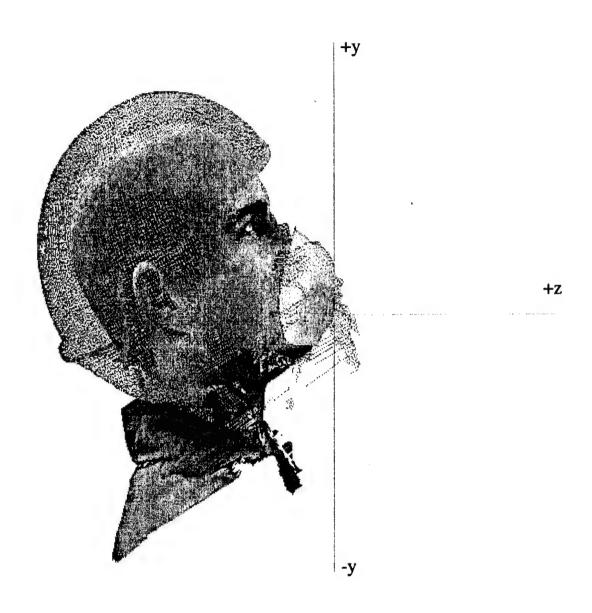

Figure 5. Unencumbered Subject Registered with Encumbered Subject and Mask

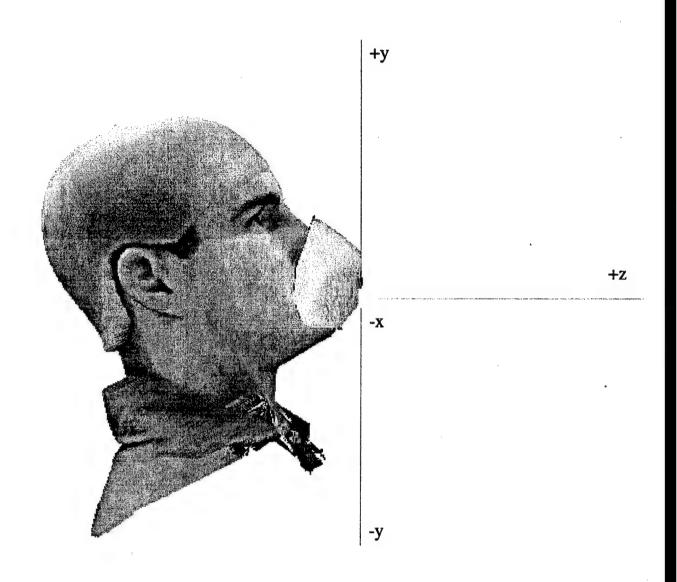

Figure 6. Unencumbered Subject Registered with Mask as Worn

The next step was to actually identify the data points on the face that contact the face piece to create the seal (the mask-to-face interface). Software was written to locate points on the face closest (within predefined angular constraints) to those points that define the outer edge of the seak face piece. All data points within three millimeters of the seal area's outer edge were then selected to represent the shape of the mask-to-face interface. These seal areas were visually checked for extrandous data points, and were subsequently edited if necessary. Finally, the three-dimensional coordinate locations of each of the points were written to an output file to be used in shape analysis. For a brief description of this software, see Appendix H.

SHAPE DESCRIPTION

Given the types of reported fitting problems, it was suggested that the traditional anthropometry may not provide enough information to determine why some subjects received good fits in the mask and others did not, and whether to adjust, reclassify, or add sizes. Rectangular coordinates from the 3-D scans collected in the field provide the shape information needed to fill in the knowledge gaps and to help make useful decisions. One method of describing shape involves utilizing the 3-D location of homologous anatomical landmarks. Another method is curvature analysis of the mask-to-face interface contour.

Distances Between Landmarks

There were fourteen points from the hard shells and sixteen anatomical landmarks which could be considered as homologous landmarks from subject to subject. Appendix I contains the list of these landmarks and a diagram showing their location. XYZ coordinates were obtained for each of the thirty points that were used. Distances between these points were converted to Euclidean distances using the Euclidean distance formula:

(1)
$$d(i,j) = \sqrt{(x_j - x_i)^2 + (y_j - y_i)^2 + (z_j - z_i)^2}$$
 which is the distance from the ith point to the jth point.

Curvature and Torsion

Curvature and torsion are two common measurements used to describe a curve. In this case, the curve is the contour of the mask-to-face interface. The motion of curvature around a curve can be illustrated by a hinge joint with movement in only one plane. The motion of torsion around a curve can be illustrated by a ball joint; its motion can move outside the plane. Formal mathematical definitions for curvature and torsion can be found in any textbook on vector calculus.

Curvature analysis refers to the computation of curvature and torsion. It begins with the parametric polynomial representation of the mask-to-face contour with respect to proportional arc length, s. One contour is represented by three polynomials: X(s), Y(s), and Z(s). These polynomials are then used to compute curvature and torsion at each point along the arc.

Some processing was necessary in order to get the data ready for curvature analysis. The contour is made up of 3-D points, but each point must be described in terms of arc length. The arc length between each successive point in the contour was estimated using the Euclidean distance formula. The proportional arc lengths were then computed at each point along the contour.

Two methods of computing the parametric polynomials were examined: regression and splines.

Regression analysis was used to compute cubic polynomial parametric equations for x, y, and z as a function of proportional arc length, s, in the mask axis system. Several attempts were made to find a good fit for one subject. First, 100% of the arc was examined. This resulted in one set of parametric equations

to fit the entire data set. The parametric equations were then used to calculate predicted values of x, y, and z coordinates at s. Figures 7, 8, and 9 are bivariate plots of the x, y, z coordinates against s, respectively. The asterisks indicate the actual x, y, or z coordinate values at s and the P's indicate the predicted x, y, or z coordinate values at s. A good fit to the data would be indicated by a close alignment of the P's with the asterisks. It is clear that these parametric equations do not provide a good fit to the data.

The data for one subject were then examined for right/left symmetry by comparing the absolute mean values for x, y, and z on the right and left side of the arc (50% of the data on either side of the face). The absolute mean values as given in Table 1 do indicate right/left symmetry at least for that subject, so 50% of the data were used to compute parametric equations. However, this also resulted in a poor fit to the data.

TABLE 1

Comparison of Right and Left Absolute Mean Values (data are in millimeters)

	X	Y	Z
Right	25.48	51.35	50.67
Left	23.67	51.92	50.01

Next, 30% of the data were used with no better fit to the data. Finally, the data were broken into segments of 0% to 15% and 15% to 30%. This gave two sets of parametric equations, one for each segment. Appendix J contains Figures J1 through J6, showing that these equations appeared to provide a good data fit for the subject. Figures J1, J2, and J3 are bivariate plots of actual and predicted data for 0% to 15% of the arc. Figures J4, J5, and J6 are bivariate plots of actual and predicted data for 15% to 30% of the arc. Curvatures and torsions were then computed using each set of parametric equations at points equally spaced along the arc. The results showed that the curvatures and torsions were non-continuous at the segment endpoints (i.e., the torsion for the first set of parametric equations ending at 15% had a positive sign, while the torsion for the second set of equations beginning at 15% had a negative sign). It was determined that the regression methodology did not allow the segment endpoints to connect, thereby causing the break in continuity in the curvature and torsion values.

Quintic splines are continuous at the first, second, and third derivatives, eliminating the discontinuity problem. The SAS/INSIGHT module (Statistical Analysis Software, 1995) provided the means to fit splines to data; however, it was unable to output the polynomials associated with the splines. L.S.A. (Nurre, 1995) was used to output the polynomials. The first task was to determine the number of control points (or the number of splines) to fit the data. An attempt was made to use SAS to determine these two parameters by reasoning that the degrees of freedom in SAS would be equal to the number of control points requested by L.S.A. As it turns out, this is not the case. Furthermore, there is no way to relate the SAS output to input for L.S.A., so SAS was abandoned. After experimenting in L.S.A. with the arc data sets for three subjects, the number of control points (100) and the smoothness parameter (the smallest available) were selected by visual inspection. A set of polynomials for each segment between control points was generated for each subject. Since there are 100 control points, there are 100 sets of polynomials per subject. The smallest smoothness parameter gave the smallest error in fit. Figures J7, J8, and J9 in Appendix J are snapshots of the screens generated by L.S.A. for one subject showing the spline fits of x, y, and z as a function of s, respectively. Figure J10 is a snapshot of the x, y, z spline fits viewed simultaneously; you can see the outline of the mask seal area as if you were looking at the subject. An advantage is that the actual data points and the line through them shows the spline fit. The same number of control points and the same smoothness parameter were applied to each subjects' data.

The polynomials were then used to resample the data so that there would be the same number of points per subject (800) and to ensure that the proportional arc lengths were homologous between subjects. Finally, curvature and torsion were computed for each resampled point.

The polynomials were also used to compute critical points on the contour. Critical points are local minimums and maximums. They are found by computing the first derivatives at each successive point and comparing them to adjacent derivatives. If the derivative at the previous point, say k-1, is positive and at k+1 the derivative is negative, then there is a local maximum at point k. Similarly, there is a local minimum at point k if the derivative at k-1 is negative and the derivative at k+1 is positive.

The idea was to reduce the number of data points required for statistical analysis to just the number of critical points to be found. Figures J11 through J13, also in Appendix J, are bivariate plots of the critical points on x(s), y(s), and z(s) for one subject. Critical points are indicated by asterisks, showing that several critical points are found that may not be 'critical' to our analysis because of noise in the data, where they are located, etc. There is really no way to weed these points out. Furthermore, there was no way to combine the information from the three sets of polynomials to determine if a critical point was critical for more than one axis. Computed critical points, therefore, were abandoned.

DATA ANALYSIS

Four different statistical methods were used in this study: 1) Analysis of Variance (ANOVA) and Multivariate Analysis of Variance (MANOVA), 2) Principal Component Analysis (PCA), 3) Euclidean Distance Matrix Analysis (EDMA), and 4) Radial Difference Mapping (RDM). These analyses focused on variation in the 2-D and 3-D data caused by wearing different mask sizes, and on variation affecting overall score.

ANOVA/MANOVA

Analysis of Variance (ANOVA) and Multivariate Analysis of Variance (MANOVA) were conducted using all traditional anthropometric measurements. (An explanation of the need for a multivariate technique to examine this data and a description of MANOVA are given in Crist et al., 1995.) The analysis looked at the mean values of subjects grouped by mask size and overall score. The analyses were used to determine three things: 1) whether there are significant differences in measurements between subjects wearing different sizes; 2) whether there are significant differences in measurements between subjects with different overall scores; and 3) whether there are significant differences in subjects' measurements between passes and fails which are dependent on the mask size. For these analyses, alpha was set at .05 and Type IV sums of squares were used for testing.

Several statistical analyses were performed using 3-D data. The purpose of these analyses was to determine 1) differences in face shape between passing and failing subjects, 2) differences in face shape between subjects wearing different sizes, and 3) differences in the four mask sizes themselves.

PRINCIPAL COMPONENT ANALYSIS

Principal Component Analysis (PCA) (Mardia et al., 1979; Johnson and Wichern, 1988) was performed on the facial contours represented by curvature and torsion. PCA is a multivariate technique that seeks to find p principal components for a data set with p variables. Each principal component is a linear combination (with unit length) of the original variables. The coefficients of the principal components are the eigenvectors of the correlation matrix. The eigenvalues are equal to the variances of the components. In this application, the first and second principal components are of interest. The first component is the linear combination of p variables with the largest variance. The second component has the second largest

variance and is perpendicular and not correlated to the first component. When the first two components provide a good fit to the data, they will explain a large percentage of the overall variance between subjects. Finally, the magnitude and direction of the coefficients of each component are examined. The coefficients of largest magnitude indicate the locations (represented by proportional arc length) on the contour that are most important in discriminating between subjects. The direction of the coefficients indicates the relationship of the coefficients to one another. For instance, all positive coefficients would indicate a general increase in curvature and/or torsion. A mixture of positive and negative coefficients would indicate that some locations on the contour significantly increase in curvature and/or torsion while others significantly decrease.

The unique feature of this PCA is that the actual contours of the four masks were included in the analysis. Plots of the data against the first two components were generated. It was thought that the subjects would cluster around the mask representing the size they wore, and that within those clusters, a pattern in the distribution of passes and fails might emerge. These results could then be traced back to the original data to indicate anthropometric differences between passing and failing subjects.

Notably, PCA for the entire data set (800 curvatures and 800 torsions per subject) required more computer memory than was available. Therefore, 30% of the data (240 curvatures and 240 torsions per subject) starting at the apex of the nose were analyzed. Again, the assumption of right/left facial symmetry is required for this analysis.

EUCLIDEAN DISTANCE MATRIX ANALYSIS

Euclidean Distance Matrix Analysis (EDMA) is a coordinate-free approach to shape comparisons using homologous landmark data. (For a detailed description of EDMA, see Lele, 1991, and Lele and Richtsmeier, 1991.) The XYZ coordinates of numbered landmarks were used for the EDMA. The Euclidean Distance Matrix (EDM) for these landmarks is then the matrix where the (i,j) entry is simply d(i,j) as given by the Euclidean distance formula (See Figure 10). Thus, if one was interested in the distance from the third landmark to the fifteenth landmark, the (3,15) entry in the EDM would be the answer.

	d(1,1) d(2,1)	d(1,2) d(2,2)	d(1,3) d(2,3)	•••	d(1,30) d(2,30)
EDM=		:	:	:	:
	:	:	:	:	: /
	d(30,1)	d(30,2)	d(30,3)	•••	d(30,30)

Figure 10. Euclidean Distance Matrix

Since the distance from the i^{th} landmark to the j^{th} landmark is the same as the distance from the j^{th} landmark to the i^{th} landmark, this is a symmetric matrix with zeros on the diagonal. This can easily be seen in Figure 10.

The Form Difference Matrix (FDM) denoted by D(X,Y) is computed by taking the ratio, element by element, from one EDM (F(X)) to another EDM (F(Y)). The (i,j) element of the FDM is the (i,j) element of F(X) divided by the (i,j) element of F(Y). The formula for the FDM is: $D(X,Y) = \frac{F_{i,j}(X)}{F_{i,j}(Y)}$ where

0/0=0. Since D(X,Y) is a symmetric matrix with zero diagonal, only the upper diagonal part is necessary to study the form difference. The elements of the FDM are the percentage change in the distances between landmarks used. Interpretation of these changes depends on the application. Any ratio smaller than 1 indicates the distance in F(Y) between the i^{th} and j^{th} landmarks is larger than the distance in F(X).

Similarly, any ratio larger than 1 indicates the distance in F(Y) is smaller than the distance in F(X). The ratios from these FDMs which are "substantially larger or substantially smaller than 1" (Lele and Richtsmeier, 1991) are then the ratios of interest which denote the areas of the greatest amount of change. As with the interpretation of the changes, the interpretation of "substantial" is also application dependent.

Each subject in this study has an associated EDM. EDMs of subjects who wore the same size and had the same type of fit are then averaged together by gender to obtain one EDM for each category of fit within a size by gender. For example, all men who wore an SN mask and received a good fit were averaged into one EDM. The differences of interest are between the subjects who received a good fit and those who received a poor fit. Consider the EDM for males in a size SN who received a good fit (call it F(X)) and the EDM for males in a size SN who received a poor fit (F(Y)). The FDM is F(X)0 given by the formula above. Thus, the FDM looks at the differences within the SN size between the men who received a good fit and the men who received a poor fit. In looking for ratios substantially larger or substantially smaller than 1, the changes of interest were restricted to those greater than 20%, i.e. ratios smaller than .80000 and greater than 1.25000.

RADIAL DIFFERENCE MAPPING

Radial difference mapping is a process that compares radial distances from a data point on one object to its counterpart on a different object (Whitestone, 1994). The output provides both a visual, in the form of a topographical-type map, and quantitative description of the radial differences between two or more objects. It was hoped that, by observing radial difference maps (RDMs) of the faces of subjects that received good fits in a mask versus those that received poor fits, clues to critical facial shape differences would become more obvious. To explore this possibility, RDMs for three subjects that received a good fit in the MN mask were compared to three subjects that received poor fits in the same size. All subjects' faces were compared to a benchmark subject, who, based upon fit scores, received the best overall fit in the MN mask (Figure 11).

Colors were selected to represent different three-millimeter intervals (e.g., dark green represents all data points on one object zero to three millimeters farther away from the reference object, blue represents all data points on one object three to six millimeters away, etc.). See Table 2 for the complete RDM key. Of the six subjects examined, no obvious patterns in the RDMs stood out as discriminating evidence of fit differences; therefore, radial difference mapping was not continued on a larger scale.

TABLE 2.

Key for Radial Difference Mapping

RADIAL DIFFERENCE MAP KEY					
COLOR	DISTANCE FROM REFERENCE OBJECT				
Violet	> 9 mm				
Indigo	6-9 mm				
Blue	3-6 mm				
Dark Green	0-3 mm				
Bright Green	0 - (-3) mm				
Yellow	-3 - (-6) mm				
Orange	-6 - (-9) mm				
Red	< -9 mm

RESULTS

SUMMARY STATISTICS

Thirty male and 30 female subjects were tested. Appendix K contains tables of summary statistics for the subjects. Tables K1 through K5 show the frequency distributions for demographic data. Most of the subjects were white. There was a broad distribution of ages for males, but a large percentage of females were 22 and 23 years old. This is explained by the fairly recent entry of females into the pilot program. Tables K6 and K7 contain summary statistics for their traditional anthropometry.

Table 3 shows the frequency of subjects by mask size.

	Total	2	8	10	40	60			

Figures 12 and 13 show the distribution of subjects by mask size (based on Sellion-Supramenton Length and Bizygomatic Breadth) and sex.

Male and female subjects were grouped into "pass/fail" categories based on the leakage, comfort, and slippage fit test ratings felt to be most relevant and reliable. Area leakage and comfort ratings and overall slippage ratings were measured on a scale from 1 to 4 where 3 (moderate problems) and 4 (excessive problems) are considered fails. Overall leakage ratings are measured on a scale from 1 to 5 where 4 (fair) and 5 (poor) are fails. Overall comfort ratings are also measured on a scale from 1 to 5; however, 3 (moderately uncomfortable), 4 (very uncomfortable), and 5 (hot spots) are considered fails. A subject who failed on any one of the area leakage or comfort ratings failed overall. A subject who failed only on slippage did not fail overall, because slippage is not considered as critical to fit as the other ratings. Examining who failed what and where could help us design a better fitting mask.

	Total	4	7	1	0	0	2	14	

Of the 29 females in size SN, there were 4 failures. Three of those failures were due to discomfort. One failure was due to a leak in the chin area. One female wearing size MN failed due to slippage and to a leak on the left side of the nose.

FIT ASSESSMENT AT HIGH-G

Ideally, all 60 subjects would have had PPG experience at a minimum of 9 G. Subjects with both PPG and high-G experience were rare, however, particularly among females. Twenty-six males and two females had some combination of the desired experience. Twenty males had sorties in a fighter: 16 to 9G (one without PPG) and 4 to 7G (two without PPG). Six males had experience with centrifuge rides to 9G. Two females had experience with centrifuge rides to 9G. Tables 6 and 7 show the effect of PPG experience on overall score. Subjects who have no PPG experience tend to pass more often than fail. This is especially true with the females who have little or no experience.

The measurement for Sellion-Supramenton was compared to the T.O. criteria for assigning mask size based on Sellion-Supramenton (SN: less than 87mm, MN and MW: 87 to 100 mm, LW: greater than 100 mm). Of the 30 male subjects, seven (23.3%) were tested in sizes other than their T.O. size. They are shown in Table 8.

TABLE 8

Frequency of Subjects Not Tested in T.O. Size

TESTED SIZE	T.O. SIZE	OVERALL SCORE	FREQUENCY
MW	SN	PASS	1
MW	LW	FAIL	1
SN	M	PASS	4
SN	M	FAIL	1

The female data is considered suspect for several reasons. Twenty-nine out of 30 female subjects wore size SN with few fails. The female data should have about the same range of variation in faces as males, and therefore, would not be expected to fit into one size, let along fit well into that size. For passing males in size SN, Bizygomatic Breadth ranges from 13.6 to 15.5 cm and Sellion-Supramenton Length ranges from 7.6 to 9.2 cm. The ranges for passing females are from 13 to 14.7 cm and from 7.5 to 8.5 cm, respectively. The ranges are similar enough that you would expect females to have a similar failure rate to males. Furthermore, few, if any, of these subjects had PPG experience, so they would not know how the fit on the ground might affect the fit at high g.

One method of fit testing is to test just one size on a random sample from the target population. The result is the quantification of the range of anthropometry where an acceptable fit in that one size is achieved and the development of a size that can be scaled up or down to generate more sizes to accommodate the expected range of variablility in the population. In this study, most all the females passed in one size. Based on that alone, one might conclude that there is no problem with the fit for these women and only one size is needed. However, we suspect that truly is not the case based on the failure rate observed in the males of similar anthropometry.

In an attempt to obtain a better distribution of passes and fails, we reevaluated the male and female data using stricter fail criteria. Slippage is ignored as a criterion. Fails for leakage and comfort in specific facial areas are 3 (slight problems), 4 (moderate problems), and 5 (excessive problems). Fails for overall leakage are 3 (OK), 4 (Fair), and 5 (Poor) and fails for overall comfort are 2 (slightly uncomfortable), 3 (moderately uncomfortable), 4 (very uncomfortable), and 5 (hot spots). The frequency of passes and fails in each size are shown in Tables 9 and 10. With the stricter criteria, nearly 87% of the males and 70% of the females are now considered fails; the proportions of both genders are skewed toward fails. These criteria obviously do not more evenly split the passes from the fails.

Total	1 3.33	29 96.67	30 100.00	

It was originally suggested that we just reevaluate the females with this criteria. We feel strongly that it would be wrong to evaluate the genders differently. It would be poor experimental and scientific practice to treat one group differently than the other to achieve the desired results. We consider the male data reliable, so we do not want to redefine the pass/fail criteria for males or females. As the female data do not contribute to the understanding of what size constitutes a good fit, the male data will be used exclusively in all further statistical analyses, and it will be assumed that any conclusions regarding the male data will be valid for females as well.

VARIATION DUE TO MASK SIZE

An important step in the analysis was to determine exactly how the four mask sizes differ in shape. Three areas of the masks were identified that were thought to be critical to its shape. They are the face length, face breadth, and nasal root breadth. Visual inspection of the masks showed that:

- MN and MW are the same in face length. SN is the shortest of the masks, and LW is the longest of the masks.
- SN and MN are virtually the same in face width. MW is only slightly wider than MN. LW is obviously much wider than the other masks.
- MW appeared the narrowest in the area of the nasal root. Generally, no differences were found between LW, MN, and SN. It is suspected that the difference in MW is not important.

Plots of frontal views, x and y coordinates (Figure 14) of the four masks bear out these observations, as does MANOVA. Euclidean Distance Matrix Analysis was used to quantify these differences.

EDMA was able to quantify the differences between the sizes by looking at the distances between the landmarks on the masks. Only the distances involving the landmarks on the perimeter of the masks were looked at since it was thought that these should be the ones that matter in the fitting process. Face length was measured from the points TOP-MID MASK to BOTTOM-MID MASK. Face width was measured at the widest points, MAX LEFT to MAX RIGHT. See description in Appendix E and mask picture in Appendix I for location of points.

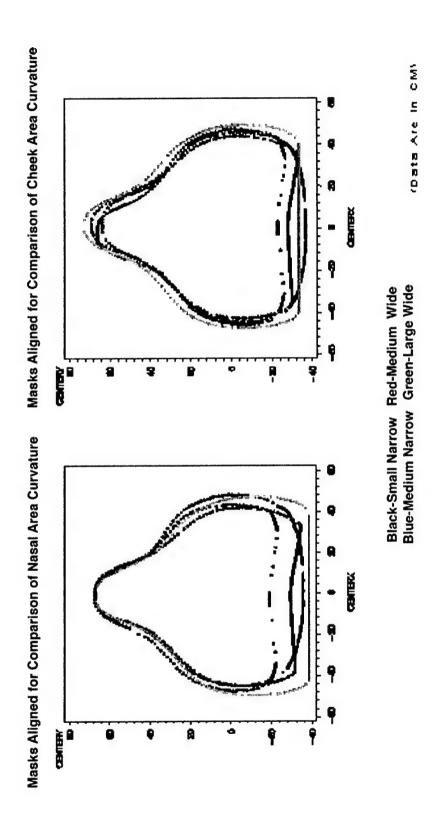

Figure 14. Comparison of the Four Mask Sizes

EDMA showed that, indeed, SN is the shortest mask in face length with SN 95% as long as MN, 94% as long as MW and 83% as long as LW. Also, LW is the longest in face length by 17% longer than SN, 13% longer than MN and 12% longer than MW.

SN and MN are almost identical in face width with SN .2% wider than MN. Thus SN and MN are the narrowest at 96.5% of the MW width and 90% of the LW width. LW is the widest of all masks and is 10% wider than SN and MN and 6.5% wider than MW.

EDMA only had one landmark in the nasal root area and thus could not verify the visual comparison at that point. However, EDMA was able to determine that there was one other difference of interest. Namely, the location of the minimum points MIN RIGHT and MIN LEFT which occur almost 10 mm closer to TOP-MID MASK for the MN size than for all other sizes. This is a difference of approximately 30%. A complete description of the changes found are contained in Appendix L.

Given that there are some physical differences in the four mask sizes, anthropometric differences between subjects wearing those masks would be expected. MANOVA (Appendix M) shows that at alpha=.05, there are no significant multivariate effects on anthropometry due to mask size (Wilk's Lambda p=.3913 and Pillai's Trace p=.4348). This indicates that the mean vectors for anthropometry do not differ depending on mask size.

Univariately (Appendix N), mask size is significant for Menton-Sellion Length (p=.0013), Sellion-Supramenton Length (p=.0001), Menton-Subnasale Length (p=.0256), and Nose Length (p=.0031). This is not a surprising result given that Sellion-Supramenton Length is the measurement used in the T.O. sizing criteria, and the lengths of the rest of the mask were probably scaled based on that variable.

Tukey's multiple pairwise comparisons of size means (Appendix N) at alpha=.05 show that: 1) for Menton-Sellion Length, subjects wearing size SN are significantly smaller from subjects wearing the other three sizes; 2) for Sellion-Supramenton, subjects wearing size SN are significantly smaller than the subjects wearing the other three sizes, and subjects wearing size LW are significantly larger than those wearing the other sizes; 3) for Menton-Subnasale and Nose Length, subjects wearing size SN and LW are significantly different from each other, but not from those wearing the other sizes. As expected, subjects wearing sizes MN and MW are not significantly different in Sellion-Supramenton Lengths with means of 123.3 for MW and 121.3 for MN.

Given that there are no T.O. criteria for assigning width sizes, the size selection process may have prevented us from detecting differences in anthropometry between sizes MN and MW. It is entirely possible that sizes MN and MW are essentially the same. Five male subjects were retested. Three of them were tested in both sizes. Two were just tested in the medium size other than the one in which they were initially tested; for example, if the subject was tested in size MN during the survey, they were retested in size MW. The data are given in Appendix O and are inconclusive. It should be noted that all three of the subjects that were retested in a size changed overall score. This point will be discussed later.

Overall, the EDMA found few significant differences between subjects grouped by mask size. For a distance to be significantly different from one size to another, the percentage of change was required to be greater than 20%. Due to this requirement, the Sellion-Supramenton Lengths between sizes were just barely insignificant. If the percentage of change was lowered to approximately 16%, Sellion-Supramenton Length becomes significant. EDMA comparisons were only made between subjects who received good fits. The subjects who failed to get a good fit were not included in this analysis since it was thought that they might not truly be in the size in which they failed. (For example, a fail in SN possibly should have been in an MN.) Thus they might throw off the comparison. (ANOVA/MANOVA performed to look at the interactions is similar to this. The results are described below.) Detailed results appear in Appendix P.

VARIATION AFFECTING OVERALL SCORE ACROSS AND WITHIN SIZES

MANOVA (Appendix M) shows that overall score (Wilks' Lambda p=.1408 and Pillai's Trace p=.1408) or the interaction between mask size and overall score (Wilks' Lambda p=.2901 and Pillai's Trace p=.3600) are insignificant.

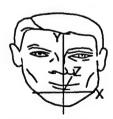

Univariately (Appendix N), overall score is significant for Head Breadth (p=.0120) and marginally significant for Bizygomatic Breadth (p=.0533). However, Tukey's multiple pairwise comparisons of mean Head Breadth and Bizygomatic Breadth between the two groups does not indicate a true significant difference at alpha=.05.

Since helmet size is determined by Head Breadth, the above result seemed to indicate that there may be some correlation between helmet size and overall score. The expert fitters at Brooks agreed that helmet size might be a factor. Twenty-seven subjects wore helmet size L. Of those, 13 passed and 14 failed. Only three subjects wore helmet size XL and all of them passed. An ANOVA (Appendix P) was conducted to examine the effect of overall score on Head Breadth for subjects wearing helmet size L. Subjects wearing helmet size XL were excluded from the analysis since none of them failed. Overall score was not significant at alpha=.05 (p=.0990). Therefore, this study provides no data to support the notion that helmet size affects fit.

Principal Component Analysis (PCA) of curvature and torsion data (Appendix Q) did not discriminate among subjects any better. The first component explained only 11% of the variation between subjects and the second component explained only 7% of the variation between subjects. Therefore, a total of 17% of the variation between subjects was explained by curvature and torsion. As expected based on this result, a plot of the first and second components did not show any pattern in the distribution of mask sizes or overall scores.

The EDMA showed that there were no significant anthropometric differences between passes and fails for subjects within a size. Interestingly, it did show that the areas of change between passes and fails within a size which were significant were non-anthropometric differences. These are all mask placement issues. Detailed results are given in Appendix R.

The two areas which the EDMA consistently showed to be the most significant areas of difference were placement of the mask top center point relative to the midpoint of the nose and placement of the bottom center point of the mask relative to promenton. These two distances were plotted against each other to look for a pattern of how the mask placement affected passes and fails. The plots of these 3-D distances showed a lot of variability in the data. Also, a band where there were no data around the zero point was noticeable. (The zero point indicates colocation with either the sellion or promenton landmark.) This gap was due to the thickness of the hard shell and face piece. Since the distance from the midpoint of the nose to the mask top center point is extremely difficult to measure, the distance from the mask top center point to sellion is being used as a reference for mask placement.

The scans of the subjects were aligned in an axis system where the Z-axis was the projection back into the head of the subject. (See Figure 15 at left.) To determine a practical method for proper mask placement, it was necessary to look at the data in 2-D. Since the largest amount of variability was due to the Z direction, only the XY coordinates were used. Only the areas which 3-D analysis had determined to be significant were looked at in the 2-D analysis.

Figure 15. Subject Alignment

RECOMMENDATIONS

Figure 16 illustrates the distance from the mask edges to sellion and promenton as well as the fit obtained by each of the men. Subjects who wear the mask such that the top of the mask is between 9 mm below sellion to 4 mm above sellion while the bottom of the mask is between 5 mm below promenton to 13 mm above promenton receive a poor fit. Thus wearing the mask in both of these areas simultaneously should be avoided. It is suspected that the underlying structure of the nose in that particular area around sellion is too bony to allow sufficient tissue deformation for a good seal. Additionally, when the bottom of the mask is in the area mentioned around promenton, it protrudes off the face. It is probable that this moves the mask off the face enough to make the lack of tissue deformation in the nose region noticeable. This lack of contact with the face probably causes an improper seal which leads to a poor fit. The 2-D analysis of the fit data simply confirms the fit area that is described in T.O. 14P3-1-161 is the proper placement for the MBU-20/P mask.

Creating New Mask Sizes

There were anecdotal recommendations from expert fitters for Small Wide (SW) and Large Narrow (LN) sizes. Due to lack of sample data for some segments of the female population, there is a possibility of an Extra Small Narrow (XSN) size being needed. No anthropometric reasons were found for these new sizes other than the fact that the sample was void of subjects with small faces. It is not unrealistic to expect that these women exist and that they will need a smaller size. If we assume that the anthropometric data for the females are reliable--that size SN fits them well--we can simply scale it down to create a smaller size. Size LN can be generated by scaling up size MN, and size LW can be generated by scaling up size MW. The following size descriptions are simply estimations.

An attempt was made to use the 3-D digitized pictures of the four current sizes for scaling purposes. We were able to obtain the XYZ coordinates of the landmarks on the hard shell of the masks. Most of these points are critical or inflection points which will help define the shape of the hard shell. The masks were placed into a common axis system defined by Bottom Midpoint of the Mask as the origin and Top Midpoint of the Mask as a point on the Y-axis and Minimum Left as an off axis but coplanar point defining the XY-plane. The masks were centered such that the landmarks were symmetric about the Y-axis. The XYZ coordinates of the referenced landmarks were then obtained for each hard shell of the current sizes.

Simple proportional growth of each landmark was computed for the new mask sizes. Landmark coordinates for LN were computed by taking the growth between SN and MN and applying it to size MN. This same growth (or shrinkage) was applied to SN to obtain the coordinates for the XSN size. For size SW, the growth between LW and MW was applied to size MW. This yielded the XYZ coordinates which can be used with the Fused Deposition Modeler® at Brooks AFB, Texas. These coordinates are provided in Appendix S.

Figure 17 shows the landmark locations in the XY plane for sizes MN, SN, and the new XSN. Size XSN is a distorted, unrealistic version of the mask. While it is shorter than sizes SN and MN, the curve around the nasal area is noticeably larger. The reason for this is that the relationship between sizes SN and MN is disproportional, as can be seen in the figure. Size SN is larger than MN around the nasal curve. That relationship was transferred to sizes SN and XSN so that the nasal curve of size XSN is larger than the curve of size SN and even larger than that of size MN. Clearly, this method of scaling works best when the relationship between the two sizes used for scaling purposes is appropriate. One way to avoid this problem may be to check the direction of the relationship for each set of landmark coordinates. In the case where SN is larger than MN in any direction, reverse the direction of the change to generate size XSN. Of course, this methodology has not been applied in practice. We recommend that the method be validated by creating and testing prototypes.

Men in All Mask Sizes - 2D Fit Data

WP = Received a Pass But in the Wrong T.O. Size
WF = Received a Fail But in the Wrong T.O. Size
PASS or FAIL = Received Score in Correct T.O. Size

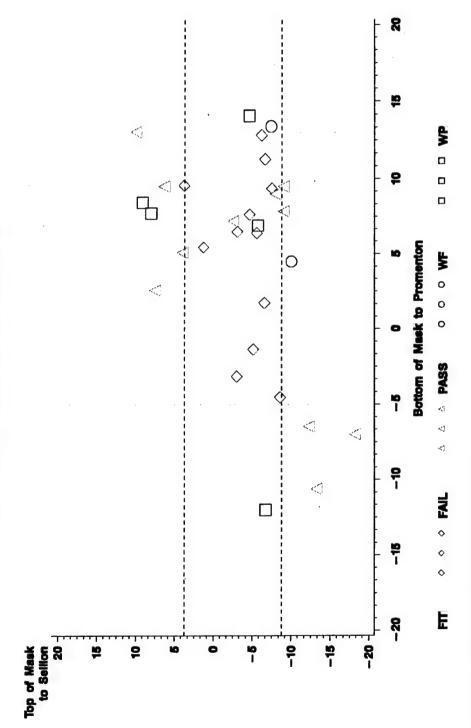

Figure 16. Men in all Mask Sizes (2-D Fit Data)

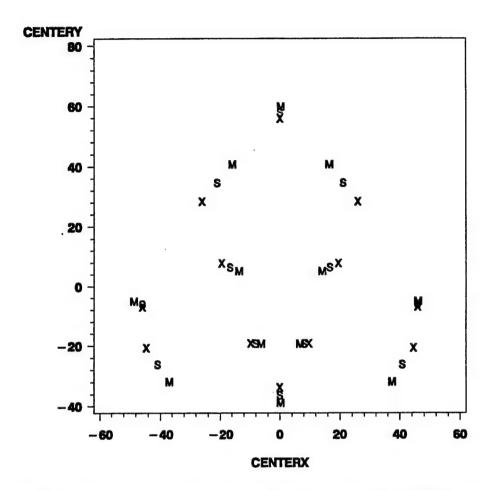

Figure 17. Comparison of Sizes Small-Narrow (S), Medium-Narrow (M), and Extra Small-Narrow (X)

CONCLUSIONS

Even though facial measurement variability was included as sampling strata, many of the strata were not filled for the women. In other words, the sampling protocol was violated in two respects for the female data. As a result, the female data are biased toward good fit, and are not adequately representative of the female population variability. It is reasonable to assume that the spread of the female data should correspond to the spread of the male data. Thus, an XSN size may be needed. Due to the sampling protocol violations, these data are unreliable, and not suitable for accurate probabilistic statements regarding fit. Furthermore, the lack of PPG experience for women rendered their fit questionnaire responses suspect. All was not in vain, however. The anthropometry of these women is still useful as one small part of a much-needed larger data base being collected for future design applications.

Complicating the analysis is the fact that compromises due to logistical limitations had to be made while planning the data collection procedures. Referring back to Figure 1 on page 2, the data collection flow chart indicates that traditional anthropometry was collected after the mask was fitted and tested on the subject and before the subject was scanned wearing it. Therefore, the subject removed the mask and then replaced it before being scanned. Before being scanned, many of the subjects did not don the mask as trained according to T.O. specifications; therefore, many were not wearing the mask for the scan the same

way they wore it when they completed the wear test and fit questionnaire. The difference in placement could mean the difference between a pass and a fail as described in the recommendations on page 29. Given the degree of mask displacement evident in the scans, the fit data may not correlate well to the mask-seal interface. Without this correlation, there is no way to truly determine what anthropometric differences exist between a pass and fail. Had we found differences, they would have been questionable.

As stated earlier, the goal of this study was to determine sizing recommendations to improve the fit of the MBU-20/P by either reshaping the existing mask or adding new sizes. The AAOM dataset, however, provided us with little or no information to make such recommendations based on anthropometry. An attempt was made to create three new sizes by applying proportional relationships between sizes to existing sizes. This method is based on the assumption that the relationships between sizes are appropriate. In this case, they were not. A technique to refine the method is suggested.

Clearly, the factor of primary importance in quality of fit within a size is the placement of the mask on the face. There were no detectable differences in facial anthropometry within a size between subjects who passed and those who failed. While no differences were found, that does not mean they do not exist. The scale of importance of the mask placement in this analysis could be masking any effects due to differences in anthropometry. Furthermore, a lack of correlation between the scan data and the fit questionnaire data may prevent detection of differences. When differences are hidden, there is no way to describe them based on statistical data.

The importance of mask placement is supported by all statistical analyses and is further supported by the small fit test (n=5) to compare sizes MN and MW. All subjects that were retested in a size changed overall score. This demonstrates that mask placement is crucial. All pilots must understand the importance of this placement, because it could mean the difference between life and death. Further fit testing with correct mask placement and proper data collection procedures may show these differences. This result can also have implications for the mask customization process. Proper adherence to the mask placement criteria in T.O. 14P3-1-161 can be used in the customization process to determine where to extract the facial contour for creating the customized mask.

APPENDIX A

Combat Edge Mask Grinding Checklist

COMBAT EDGE MASK GRINDING CHECKLIST

NAME	DATE
	TIME

Instructions: When finished fitting each pilot, indicate in the trial number the number of times you have fit this individual. Using the checklist, indicate the problems associated with each facial region, (L for leakage or P for excessive pressure), rate the severity of the problem using the scale provided, and record if grinding is required in that particular facial region. Use the last two rows to indicate your opinion as to the overall severity of leaks and pressure associated with the mask (these ratings should take all facial regions into consideration at once).

NOTE: This form should be completed the first time the pilot is fit, and each subsequent time that a pilot is seen in order to correct fit problems.

Consent Form

Protocol 83-30 (15 Feb 94)

INFORMATION PROTECTED BY THE PRIVACY ACT OF 1974

Consent Form

Volunteer signature

TITLE: ANTHROPOMETRY - Advanced Aircrew Oxygen Mask (AAOM) Program

- 1. You are invited to participate in an experiment in which we will measure the body sizes and surfaces of individuals for use in the sizing and design of clothing and personal protective equipment or of aircraft and ground equipment crew and work stations.
- 2. If you decide to participate, we will measure a number of dimensions on your body. These will describe the lengths, breadths, depths, circumferences, and surface contours of your body and its major segments. To aid in this process, measuring marks will be placed on your body with a water soluble colored pencil or gummed back stickers. These will be removed after measuring is completed. Measurements are made with several types of devices. One is a device which is similar to a yard stick called an anthropometer. Also used are tape measures and various types of calipers. Another is a light scanner which will project a line of light from a very low power laser onto your skin surface. This light will be moved around you and will be recorded in a video camera. We have measured many thousands of men and women with no adverse effects.
- 3. Your confidentiality as a participant in this program will be protected. If statistical data collected during the test program is to be published in scientific literature, it will be done so without identifying individual subjects.
- 4. If you decide to participate, you are free to withdraw your consent and to discontinue participation at any time without prejudice to your future relations with the Armstrong Laboratory. If you have any questions, please feel free to contact Kathleen M. Robinette, AL/CFHD, Building 248, 2255 H Street, Wright-Patterson AFB OH 45433-7022, (513) 255-8810.

5. I,	, am pa	articipating because I w	ant to. The decision
to participate in this resear	rch study is completely vol	untary on my part. No	one has coerced or
intimidated me into partic	ipating in this program	Capt Jeffrey W. Ho	ffmeister has
the procedures involved, v Principal Investigator or a	and all questions I have ask which are set forth above, we designee will be available as study. I understand that it	which I have read. I und to answer any questions	lerstand that the s concerning

this research which may relate to my decision to continue participation, I will be informed. I further understand that I may withdraw this consent at any time and discontinue further participation in this study. I also understand that the Medical Consultant for this study may terminate my participation in this study if it is felt to be in my best interest.

- 6. I understand that for my participation in this project I shall be entitled to payments as specified in the DOD Pay and Entitlements Manual or in the current contracts. Or, I understand that I will not be paid for my participation in this experiment.
- 7. I understand that my participation in this study may be photographed, filmed, or audio/video taped. I further understand that the scan produces a laser image which itself is a numeric photo. I consent to the use of these media for research and training purposes and understand that any release of records of my participation in this study may only be disclosed according to federal law, including the Federal Privacy Act, 5 U.S.C. 552a, and its implementing regulations. This means personal information will not be released to an unauthorized source without my permission.

I FULLY UNDERSTAND THAT I AM MAKING A DECISION WHETHER OR NOT TO PARTICIPATE. MY SIGNATURE INDICATES THAT I HAVE DECIDED TO PARTICIPATE HAVING READ THE INFORMATION PROVIDED ABOVE.

Combat Edge Fit Assessment Questionnaire

COMBAT EDGE FIT ASSESSMENT QUESTIONNAIRE

Name			Date		
HGU-55/P HELMET SIZE:					
COMBAT EDGE MASK SIZ	E: SNar MNar	MWide	LWide		
How many sorties have you f	lown with the CO	MBAT ED	GE mask?		
Have you flown using PPG?	YES NO	If yes	s, how many sorties	s?	
Has the hardshell of your CO	MBAT EDGE ma	sk been gro	ound (customized)	YES	NO

Key for questions 1-3 -- 1: Comfortable, 2: Tolerable, 3: Irritating, 4: Acute and lingering pain, have to drop mask.

1. Rate each facial region for comfort of the pressure applied by the COMBAT EDGE mask...

Locations			Comfort		
(Refer to Diagram)	Comfortable	Slightly Uncomfortable	Moderately Uncomfortable	Very Uncomfortable	Hot Spot?
	1	2	3	4	
A. Bridge of Nose					
B. Right side of Nose					
C. Left side of Nose					
D. Right Cheek					
E. Left Cheek					
F. Chin					
G. Other (List)					

2. How would you rate the comfort of the COMBAT EDGE mask at high G? Highest G?

Comfortable	Slightly Uncomfortable	Moderately Uncomfortable	Very Uncomfortable	Hot Spot?
1	2	3	4	5

3. How would you rate the COMBAT EDGE mask for OVERALL COMFORT?

Comfortable	Slightly Uncomfortable	Moderately Uncomfortable	Very Uncomfortable	Hot Spot?
1	2	3	4	5

Key for question 4 -- 1: None, 2: Slight shift on face, 3: Needs repositioning, 4: Seal is broken

4a. How would you rate the SLIPPAGE of the COMBAT EDGE mask?

No Slippage	Slight Slippage	Moderate Slippage	Excessive Slippage
1	2	3	4

- 4b. If your mask slipped, at what G load did it first begin to slip? _____
- 4c. Do you think the slippage was due to a poor fit as opposed to perspiration, skin oil, etc.?

Key for questions 5-6 -- 1: None, 2: Noticeable, 3: Irritates the eyes, 4: Burns the eyes.

5. Identify the severity of leaks for each facial region.

Locations	Severity					
(Refer to Diagram)	No Leaks	Slight Leakage	Moderate Leakage	Excessive Leakage		
	1	2	3	4		
A. Bridge of Nose						
B. Right side of Nose						
C. Left side of Nose

Anatomical Landmark Description

Auxiliary Landmark Description

TRADITIONAL ANTHROPOMETRIC LANDMARK DESCRIPTIONS

FRONTOTEMPORALE (L6, L26): The point of deepest indentation of the temporal crest from the frontal bone above the brownidges.

GLABELLA (L12) - The most anterior point in the midline of the forehead between the brow ridges. Located visually and by palpation before traditional anthropometry.

INFRAMALAR (L8, L28) - The most inferior point of the zygomatic process of the maxilla. Located by palpation before traditional anthropometry.

INFRAORBITALE (L11, L22) - The lowest point on the inferior margin of the orbit or eye socket. Located by palpation before traditional anthropometry.

MENTON (L17): The inferior point of the mandible (tip of the chin) in the midsagittal plane.

NUCHALE (L33)- The lowest bony point on the base of the back of the skull in the mid-sagittal plane. Located by palpation before traditional anthropometry.

PROMENTON (L16)- The most anterior projection of the soft tissue of the chin in the mid-sagittal plane. Located visually before traditional anthropometry.

PRONASALE (L14) - The tip of the nose. Located visually before traditional anthropometry.

SELLION (L13) - The point of greatest indentation where the bridge of the nose meets the forehead (the point of greatest indentation of the nasal root depression). Located visually before traditional anthropometry.

SUPRAMENTON (L42) - The point of deepest depression under the lower lip in the midline of the face. Located visually before traditional anthropometry.

TRAGION (L1, L32) - Point located at the notch just above the tragus of each ear. this point corresponds approximately to the upper edge of the ear hole (external auditory meatus) of the skull. Located visually before traditional anthropometry.

ZYGION (L2, L29) - The most lateral point of the zygomatic arch. Located before traditional anthropometry using spreading calipers to identify widest set of points.

* Landmark names followed by two identifiers indicates "right" and "left".

AUXILIARY LANDMARKS DESCRIPTIONS

UPPER RIGHT RIVET (Z1) - The upper right rivet on the mask hardshell.

UPPER LEFT RIVET (Z2) - The upper left rivet on the mask hardshell.

UPPER RIGHT PENTAGON (Z3) - The upper right corner of the "pentagon" on the front of the MBU-20/P mask hardshell.

UPPER LEFT PENTAGON (Z4) - The upper left corner of the "pentagon" on the front of the MBU-20/P mask hardshell.

LOWER RIGHT PENTAGON (Z5) - The lower right corner of the "pentagon" on the front of the MBU-20/P mask hardshell.

LOWER LEFT PENTAGON (Z6) - The lower left corner of the "pentagon" on the front of the MBU-20/P mask hardshell.

RIGHT HELMET DIMPLE (Z7) - The lower dimple on the right side of the HGU-55/P helmet.

MID-FRONT EDGEROLL (Z8) - The mid-point of the front edgeroll on the HGU-55/P helmet.

LEFT HELMET DIMPLE (Z9) - The lower dimple on the left side of the HGU-55/P helmet.

RIGHT BAYONET (Z10) - A point on the end of the bayonet attached to the right side of the MBU-20/P mask (as worn by subject with HGU-55/P helmet).

LEFT BAYONET (Z11) - A point on the end of the bayonet attached to left side of the MBU-20/P mask (as worn by subject with HGU-55/P helmet).

MID Z1-Z2 (Z12) - The Mid-point of landmarks Z1 and Z2 (used to help define mask-axis system).

MID Z5-Z6 (Z13) - The Mid-point of landmarks Z5 and Z6 (used to help define mask-axis system).

TOP-MID MASK (Z14) - A point at the top-middle of the nose region on the MBU-20/P mask hardshell.

BOTTOM-MID MASK (Z15) - A point at the bottom-middle of the chin region on the MBU-20/P mask hardshell.

MIN RIGHT (Z16) - The minimum curvature inflection point on the right side of the MBU-20/P mask hardshell.

MIN LEFT (Z17) - The minimum curvature inflection point on the left side of the MBU-20/P mask hardshell.

MAX RIGHT (Z18) - The maximum curvature inflection point on the right side of the MBU-20/P mask hardshell.

MAX LEFT (Z19) - The maximum curvature inflection point on the left side of the MBU-20/P mask hardshell.

MAX BOTTOM-RIGHT (Z20) - The maximum curvature inflection point on the bottom-right of the MBU-20/P mask hardshell.

MAX BOTTOM-LEFT (Z21) - The maximum curvature inflection point on the bottom-left of the MBU-20/P mask hardshell.

MID-NOSEBRIDGE (Z22) - The point on the bridge of the nose half-way between Sellion and Pronasale. Located visually in three-dimensional surface scan data.

RIGHT ALARE (Z23) - The most lateral point on the right side of the nose. Located visually in threedimensional surface scan data.

LEFT ALARE (Z24) - The most lateral point on the left side of subject's nose. Located visually in three-dimensional surface scan data.

APPENDIX F

Definitions of AAOM Anthropometry

DEFINITIONS OF AAOM ANTHROPOMETRY

BI-INFRAMALAR BREADTH - The straight-line distance is measured between the right and left inframalar (the most inferior point of the zygomatic process of the maxilla) landmarks.

BITRAGION-SUBNASALE ARC - The surface distance is measured between the right and the left tragion (Tragion is the point where the top of the cartilaginous flap at the front of the ear joins the head) with a tape passing across the face at the center of the juncture of the nose with the face above the upper lip (subnasale).

BIZYGOMATIC BREADTH - The maximum horizontal distance is measured across the face between the upper cheek bones (zygomatic arches).

HEAD BREADTH - The maximum horizontal breadth of the head above the ears is measured.

HEAD CIRCUMFERENCE - The maximum circumference of the head is measured in a front-to-back plane with the tape passing just above the bony brow ridges and over the most protruding point of the back of the head.

HEAD LENGTH - The maximum straight line is measured between he most protruding point of the forehead between the brow-bridges and the back of the head.

LIP LENGTH - The subject closes the mouth with the facial muscles relaxed. The straight-line distance is measured between the corners of the mouth.

LIP LENGTH SMILING - The straight-line distance is measured between the corners of the mouth while the subject smiles broadly.

MENTON-SELLION LENGTH - The subject closes the mouth with the teeth lightly touching together. The straight-line distance is measured between the underside of the tip of the chin (menton) in the midline of the face and the point of deepest depression at the top of the nose between the eyes (sellion).

MENTON-SUBNASALE LENGTH - The subject closes the mouth with the teeth lightly together. The straight-line distance is measured between the underside of the tip of the chin (menton) in the midline of the face and the center of the bottom of the nose where it joins the face above the upper lip (subnasale).

NASAL ROOT BREADTH - The breadth of the bridge of the nose is measured at its point of deepest depression at a depth of about two-thirds the distance between the top of the bridge and the inner corner of the eyes.

NOSE BREADTH - The horizontal breadth of the nose is measured at the level of the maximum flare of the nostrils.

NOSE LENGTH - The straight-line distance is measured between the point of deepest depression at the top of the nose between the eyes (sellion) and the center of the bottom of the nose where it joins the face above the upper lip (subnasale).

NOSE PROTRUSION - The horizontal distance is measured between the center of the juncture of the bottom of the nose with the face above the upper lip (subnasale) and the tip of the nose.

SELLION-SUPRAMENTON - The subject closes the mouth with the teeth touching lightly together. The straight-line distance is measured between the point of deepest depression under the lower lip in the midline of the face (supramenton) and the point of deepest depression at the top of the nose between the eyes (sellion).

AAOM Customization and Data Extraction Software

EXTEND is a CARD Lab tool developed specifically for AAOM. It projects the edge of the mask front onto a face scan. EXTEND matches the closest point on the face to get a more "natural" fit. For instance, a proper fitting mask extends nearly perpendicular to the face in the lower half of the mask, but extends more diagonally in the nose region, since a perpendicular fit is parallel to the surface of the nose. Accepting only the closest point also fails in the nose region, because the distance from the mask to the nose is very small, and the tendency was to try to go sideways toward the nose instead of backwards toward the main face surface. Experimentation indicated that an angle of no more than 15 degrees (from perpendicular to the face) in the lower face area and no more than 45 degrees in the nose region produced a profile similar to the shape of a standard mask. Another problem that the angular allowance reduced was the problem that the outer edges of the upper region of the mask actually project into the eye sockets unless some angular tolerance is allowed.

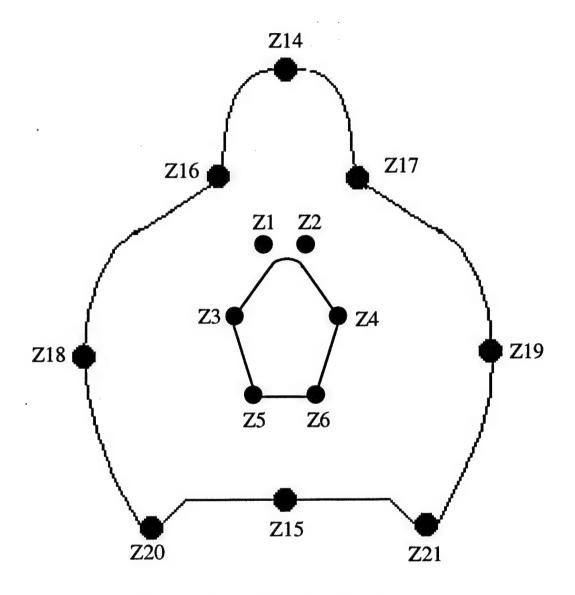

SEAL is a CARD Lab tool developed specifically for AAOM. It extracts the boundary of the seal area projected by the EXTEND tool described above and produces a set of points within the specified distance inside the seal boundary. This was used initially to extract the full area under the mask for the inside of a custom plug, but was also used later to extract just the points near the boundary for statistical analysis.

Comparing Mask Size SN to Mask Size MN

The distances from Top-Mid Mask to Min Right and Min Right to Min Left are 20% to 29% larger for SN than for MN.

The distances from Top-Mid Mask to Min Left and Bottom-Mid Mask to Max Bottom-Left are both 10% to 19% larger for SN than for MN.

The distances from Bottom-Mid Mask to Max Bottom-Right, Min Right to Max Left, Max Right to Max Bottom-Left, Max Left to Max Bottom-Right and Max Bottom-Right to Max Bottom-Left are all 1% to 9% larger for SN than MN.

The distances from Top-Mid Mask to Max Right, Top-Mid Mask to Max Left, Bottom-Mid Mask to Max Right, Min Right to Max Bottom-Left and Max Right to Max Left are virtually unchanged from SN to MN.

All of the following distances were 1%-9% smaller for SN than for MN: Top-Mid Mask to Bottom-Mid Mask, Top-Mid Mask to Max Bottom-Right, Top-Mid Mask to Max Bottom-Left, Bottom-Mid Mask to Min Right, Bottom-Mid Mask to Min Left, Bottom-Mid Mask to Max Left, Min Left to Max Right and Min Left to Max Bottom-Right.

The distances from Min Right to Max Right, Min Right to Max Bottom-Right, Min Left to Max Left and Min Left to Max Bottom-Left are 10% to 19% smaller for SN than for MN.

The distances from Max Left to Max Bottom-Left and Max Right to Max Bottom-Right are 20% to 29% smaller for SN than for MN.

Comparing Mask Size SN to Mask Size MW

The distances from Bottom-Mid Mask to Max Right, Min Right to Min Left, Min Right to Max Right, Min Left to Max Right and Max Right to Max Bottom-Right are virtually equal between the SN and MW masks.

All other distances were between 1% to 9% smaller for SN than for MW.

Comparing Mask Size SN to Mask Size LW

The distances from Max Right to Max Bottom-Right and Max Left to Max Bottom-Left are 20% to 29% smaller for SN than LW.

All of the following distances are 10% to 19% smaller for SN than LW: Top-Mid Mask to Bottom-Mid Mask, Top-Mid Mask to Max Right, Top-Mid Mask to Max Left, Top-Mid Mask to Max Bottom-Right, Top-Mid Mask to Max Bottom-Left, Bottom-Mid Mask to Min Right, Bottom-Mid Mask to Min Left, Bottom-Mid Mask to Max Right, Bottom-Mid Mask to Max Left, Min Right to Max Right, Min Right to Max Bottom-Right, Min Right to Max Bottom-Left, Min Left to Max Bottom-Right, Min Left to Max Bottom-Left and Max Right to Max Bottom-Left.

The distances from Top-Mid Mask to Min Right, Top-Mid Mask to Min Left, Bottom-Mid Mask to Max Bottom-Right, Bottom-Mid Mask to Max Bottom-Left, Min Right to Min Left, Min Right to Max Left, Min Left to Max Right, Max Right to Max Left, Max Left to Max Bottom-Right and Max Bottom-Right to Max Bottom-Left are all 1% to 9% smaller for SN than for LW.

Comparing Mask Size MN to Mask Size MW

The distances from Max Right to Max Bottom-Right and Max Left to Max Bottom-Left are 20% to 29% larger for MN than for MW.

The distances from Min Right to Max Right, Min Right to Max Bottom-Right and Min Left to Max Bottom-Left are 10% to 19% larger for MN than for MW.

The distances from Bottom-Mid Mask to Min Right, Bottom-Mid Mask to Min Left, Min Left to Max Right, Min Left to Max Left and Min Left to Max Bottom-Right are 1% to 9% larger for MN than for MW.

The distances from Top-Mid Mask to Bottom-Mid Mask, Top-Mid Mask to Max Bottom-Right and Bottom-Mid Mask to Max Right are virtually unchanged from MN to MW.

All of the following distances are 1% to 9% smaller for MN than for MW: Top-Mid Mask to Max Right, Top-Mid Mask to Max Left, Top-Mid Mask to Max Bottom-Left, Bottom-Mid Mask to Max Left, Min Right to Max Bottom-Left, Max Right to Max Right to Max Bottom-Left and Max Left to Max Bottom-Right.

The distances from Bottom-Mid Mask to Max Bottom-Right and Max Bottom-Right to Max Bottom-Left are 10% to 19% smaller for MN than for MW.

The distances from Top-Mid Mask to Min Right, Top-Mid Mask to Min Left, Bottom-Mid Mask to Max Bottom-Left and Min Right to Min Left are 20% to 29% smaller for MN than for MW.

Comparing Mask Size MN to Mask Size LW

The distances from Min Right to Max Right and Max Left to Max Bottom-Left are 1% to 9% larger for the MN than the LW.

The distances from Bottom-Mid Mask to Min Left, Bottom-Mid Mask to Max Left, Min Right to Max Bottom-Right, Min Left to Max Right, Min Left to Max Bottom-Right are 1% to 9% smaller for the MN than the LW.

All of the following distances are 10% to 19% smaller for MN than for LW: Top-Mid Mask to Bottom-Mid Mask, Top-Mid Mask to Max Right, Top-Mid Mask to Max Left, Top-Mid Mask to Max Bottom-Right, Top-Mid Mask to Max Bottom-Left, Bottom-Mid Mask to Min Right, Bottom-Mid Mask to Max Right, Bottom-Mid Mask to Max Bottom-Right, Min Right to Max Left, Min Right to Max Bottom-Left, Max Right to Max Bottom-Left, Max Left to Max Bottom-Right and Max Bottom-Right to Max Bottom-Left.

The distances from Top-Mid Mask to Min Right, Top-Mid Mask to Min Left, Bottom-Mid Mask to Max Bottom-Left and Min Right to Min Left are 20% to 29% smaller for MN than for LW.

Comparing Mask Size MW to Mask Size LW

The distances from Top-Mid Mask to Min Left and Bottom-Mid Mask to Max Bottom-Right are 1% to 9% larger for MW than for LW.

The distances from Bottom-Mid Mask to Max Left, Bottom-Mid Mask to Max Bottom-Left, Min Right to Max Bottom-Left, Max Left to Max Bottom-Right and Max Bottom-Right to Max Bottom-Left are virtually equal for MW and LW.

All of the following distances are 1% to 9% smaller for MW than for LW: Top-Mid Mask to Min Right, Top-Mid Mask to Max Right, Top-Mid Mask to Max Left, Bottom-Mid Mask to Max Right, Min Right to Min Left, Min Right to Max Left, Min Left to Max Right, Min Left to Max Left, Min Left to Max Bottom-Right, Max Right to Max Left and Max Right to Max Bottom-Left.

The distances from Top-Mid Mask to Bottom-Mid Mask, Top-Mid Mask to Max Bottom-Right, Top-Mid Mask to Max Bottom-Left, Bottom-Mid Mask to Min Right, Bottom-Mid Mask to Min Left, Min Right to Max Right, Min Right to Max Bottom-Left and Max Left to Max Bottom-Left are 10% to 19% smaller for MW than for LW.

The distance from Max Right to Max Bottom-Right is 27% smaller for MW than for LW.

APPENDIX O

Fit Comparison of Sizes MN and MW

FIT COMPARISON OF SIZES MN AND MW

The raw data for the fit comparison of sizes MN and MW are located in the tables on the following page. All columns after the Survey Size column contain fit information. Within each column is data for up to three tests, each divided by a slash (/). The first number is the test rating for the main survey; it is highlighted. The second number is the test rating in size MN for the small survey. If the mask size tested in the main survey was MN, this number is highlighted. The third number is the test rating in size MW for the small survey. If the mask size tested in the main survey was MW, this number is highlighted. Two subjects (39 and 45) were not retested in the same size they wore in the main survey (MN); the missing information is indicated by a dash (-). All other subjects were retested.

APPENDIX R

Euclidean Distance Maxtrix Analysis Results

EDMA RESULTS

Variation Due to Mask Size

Males with Good Fits - Ratio of SN to MN

All significant distances that were found in the comparison of good fits in a size SN to good fits in a size MN were distances between a facial landmark and a mask landmark. None were anthropometric differences.

The distance from Upper Left Rivet to Pronasale is 30%-39% larger for males wearing SN than for males wearing MN.

The distances from Top-Mid Mask to Min Right, Top-Mid Mask to Pronasale, Min Right to Min Left, Max Bottom-Left to Promenton, Max Bottom-Left to Supramenton are 20%-29% larger for males wearing SN than for males wearing MN.

The distance from Top-Mid Mask to Mid-Nosebridge is 40%-49% larger for males wearing SN than for males wearing MN.

The distances from Bottom-Mid Mask to Supramenton, Min Left to Left InfraOrbitale, Max Right to Right InfraMalar are 30%-39% smaller for males wearing SN than for males wearing MN.

The distances from Min Right to Right InfraOrbitale, Max Right to Max Bottom-Right, Max Left to Max Bottom-Left, Max Left to Left InfraMalar, Max Bottom-Right to Right InfraMalar, Max Bottom-Right to Right InfraOrbitale, Max Bottom-Left to Left InfraMalar are 20%-29% smaller for males wearing SN than for males wearing MN.

Males with Good Fits - Ratio of SN to MW

Comparing males in size SN with good fits to males in size MW with good fits again showed that all of the differences were due to the mask differences. No anthropometric significant differences were found.

Several distances are 20%-29% smaller for males wearing SN than for males wearing MW. They are: Upper Right Rivet to Mid-Nosebridge, Upper Left Rivet to Mid-Nosebridge, Upper Right Pentagon to Mid-Nosebridge, Upper Right Pentagon to Pronasale, Lower Right Pentagon to Mid-Nosebridge, Lower Right Pentagon to Pronasale, Lower Left Pentagon to Pronasale, Bottom-Mid Mask to Left Alare, Min Right to Mid-Nosebridge, Min Right to Glabella, Min Left to Left InfraOrbitale, Max Right to Right Alare, Max Right to Right InfraOrbitale, Max Bottom-Right to Right Alare, Max Bottom-Right to Right InfraOrbitale, Max Bottom-Left to Left InfraOrbitale, and Max Bottom-Left to Left InfraOrbitale, and Max Bottom-Left to Left InfraMalar.

The distance from Min Right to Sellion is 30%-39% smaller for males wearing SN than for males wearing MW.

The distances from Bottom-Mid Mask to Supramenton, Max Right to Right InfraMalar, and Max Left to Left InfraMalar are 40%-49% smaller for males wearing SN than for males wearing MW.

The distances from Upper Left Pentagon to Promenton, Lower Right Pentagon to Bottom-Mid Mask, Lower Left Pentagon to Promenton, and Top-Mid Mask to Right InfraOrbitale are 20%-29% larger for males wearing SN than for males wearing MW.

The distances from Top-Mid Mask to Mid-Nosebridge, Min Right to Right Alare, and Min Right to Right InfraMalar are 30%-39% larger for males wearing SN than for males wearing MW.

The distance from Min Left to Left Alare is 40%-49% larger for males wearing SN than for males wearing MW.

Males with Good Fits - Ratio of SN to LW Sizes

In comparing males in size SN with good fits to the one male in size LW with good fit the following anthropometric differences were found to be significant: Right Alare to Supramenton, Right Tragion to Right Zygion, Pronasale to Promenton, and Pronasale to Supramenton. These distances are all 20%-29% smaller for males wearing SN masks than for the one male wearing the LW size.

Several distances are 20%-29% smaller for males wearing SN masks than for the male wearing the LW size. They are: Upper Right Rivet to Upper Right Pentagon, Upper Right Rivet to Top-Mid Mask, Upper Left Rivet to Top-Mid Mask, Upper Right Pentagon to Top-Mid Mask, Upper Left Pentagon to Top-Mid Mask, Lower Right Pentagon to Promenton, Top-Mid Mask to Pronasale, Top-Mid Mask to Supramenton, Min Right to Mid-Nosebridge, Min Right to Pronasale, Min Right to Promenton, Min Right to Supramenton, Min Left to Left Alare, Min Left to Supramenton, Max Right to Max Bottom-Right, Max Left to Max Bottom-Left, Right Alare to Supramenton, Right Tragion to Right Zygion, Pronasale to Promenton, and Pronasale to Supramenton.

The distances from Top-Mid Mask to Mid-Nosebridge, and Bottom-Mid Mask to Promenton are 30%-39% smaller for males wearing SN masks than for the male wearing the LW size.

The distances from Upper Right Rivet to Pronasale, Upper Left Rivet to Mid-Nosebridge, and Upper Left Rivet to Pronasale are 20%-29% larger for males wearing SN masks than for the male wearing the LW size.

The distance from Upper Right Rivet to Mid-Nosebridge is 30%-39% larger for males wearing SN masks than for the male wearing the LW size.

The distances from Top-Mid Mask to Glabella, and Top-Mid Mask to Sellion are 40%-49% larger for males wearing SN masks than for the male wearing the LW size.

Males with Good Fits - Ratio of MN to MW Sizes

There was a significant anthropometric difference found when comparing males with good fits in the MN size to males with good fits in the MW size. That difference was Glabella to Sellion which was 20%-29% smaller for males wearing the MN size than for the males wearing the MW size. However this difference would not appear to have any significance in determining mask width for sizing purposes.

Several distances are 20%-29% smaller for males wearing the MN size than for the males wearing the MW size. They are: Upper Left Rivet to Min Right , Upper Left Rivet to Mid-Nosebridge, Upper Left Rivet to Pronasale, Top-Mid Mask to Min Right , Top-Mid Mask to Min Left , Bottom-Mid Mask to Max Bottom-Left, Min Right to Min Left , Min Right to Glabella, Min Right to Sellion, Min Right to Pronasale, Max Right to Right InfraMalar, Max Left to Left InfraMalar, Max Bottom-Left to Supramenton, and Glabella to Sellion.

The distances from Lower Right Pentagon to Lower Left Pentagon, and Min Right to Mid-Nosebridge are 30%-39% smaller for males wearing the MN size than for the males wearing the MW size.

The distances from Lower Right Pentagon to Bottom-Mid Mask, Max Right to Max Bottom-Right, and Max Left to Max Bottom-Left are 20%-29% larger for males wearing the MN size than for the males wearing the MW size.

The distances from Min Right to Right Alare, Min Right to Right InfraMalar, Min Right to Right InfraOrbitale, and Min Left to Left Alare are 30%-39% larger for males wearing the MN size than for the males wearing the MW size.

Males with Good Fits - Ratio of MN to LW Sizes

The only anthropometric difference between the males in size MN with good fits and the male in size LW with good fit is the distance from Glabella to Sellion which is 20%-29% smaller for the males wearing MN than for the one male wearing the LW size.

Several distances are 20%-29% smaller for the males wearing MN than for the male wearing the LW size. They are: Upper Left Rivet to Top-Mid Mask, Upper Left Rivet to Min Right, Upper Right Pentagon to Top-Mid Mask, Upper Left Pentagon to Lower Left Pentagon, Lower Right Pentagon to Promenton, Lower Left Pentagon to Promenton, Top-Mid Mask to Min Right, Top-Mid Mask to Min Left, Top-Mid Mask to Right Alare, Top-Mid Mask to Left Alare, Top-Mid Mask to Promenton, Bottom-Mid Mask to Max Bottom-Left, Bottom-Mid Mask to Promenton, Min Right to Min Left, Min Right to Right Alare, Min Right to Left Alare, Min Right to Supramenton, Min Left to Mid-Nosebridge, Min Left to Left Alare, Min Left to Left InfraOrbitale, Max Bottom-Left to Promenton, Max Bottom-Left to Supramenton, and Glabella to Sellion.

The distances from Min Right to Mid-Nosebridge, Min Right to Pronasale, and Min Left to Pronasale are 30%-39% smaller for the males wearing MN than for the male wearing the LW size.

The distance from Top-Mid Mask to Pronasale is 40%-49% smaller for the males wearing MN than for the male wearing the LW size.

The distance from Top-Mid Mask to Mid-Nosebridge is 60%-69% smaller for the males wearing MN than for the male wearing the LW size.

The distances from Upper Right Rivet to Sellion, Upper Left Rivet to Promenton, Upper Left Rivet to Sellion, and Max Left to Left InfraMalar are 20%-29% larger for the males wearing MN than for the male wearing the LW size.

The distance from Min Right to Right InfraOrbitale is 30%-39% larger for the males wearing MN than for the male wearing the LW size.

The distances from Upper Right Rivet to Mid-Nosebridge, Bottom-Mid Mask to Supramenton, and Max Right to Right InfraMalar are 40%-49% larger for the males wearing MN than for the male wearing the LW size.

The distances from Top-Mid Mask to Glabella, and Top-Mid Mask to Sellion are 50%-59% larger for the males wearing MN than for the male wearing the LW size.

Males with Good Fits - Ratio of MW to LW Sizes

There are two significant anthropometric differences between the males with good fits in size MW and the male with good fit in size LW. The distance from Pronasale to Supramenton is 20%-29% smaller for the males wearing the MW mask than for the male wearing the LW size. However, the distance from Right Zygion to Right InfraMalar is 20%-29% larger for the males wearing the MW mask than for the male wearing the LW size. The distance from Right Zygion to Right InfraMalar should not make a difference in mask size.

Several distances are 20%-29% smaller for the males wearing the MW mask than for the male wearing the LW size. They are: Upper Right Rivet to Promenton, Upper Right Rivet to Supramenton, Upper Left Rivet to Promenton, Upper Left Rivet to Supramenton, Upper Right Pentagon to Promenton, Upper Right Pentagon to Supramenton, Upper Left Pentagon to Promenton, Upper Left Pentagon to Supramenton, Lower Right Pentagon to Supramenton, Lower Right Pentagon to Supramenton, Top-Mid Mask to Right Alare, Top-Mid Mask to Left Alare, Top-Mid Mask to Right InfraMalar, Top-Mid Mask to Right InfraMalar, Top-Mid Mask to Promenton, Top-Mid Mask to Supramenton, Min Right to Pronasale, Min Right

to Promenton, Min Left to Promenton, Min Left to Left InfraMalar, Max Right to Max Bottom-Right, Max Right to Promenton, Max Right to Supramenton, and Pronasale to Supramenton.

The distances from Lower Right Pentagon to Bottom-Mid Mask, Lower Right Pentagon to Promenton, Lower Left Pentagon to Promenton, Top-Mid Mask to Pronasale, Min Right to Right InfraMalar, Min Right to Supramenton, Min Left to Pronasale, and Min Left to Supramenton are 30%-39% smaller for the males wearing the MW mask than for the male wearing the LW size.

The distance from Min Right to Right Alare is 40%-49% smaller for the males wearing the MW mask than for the male wearing the LW size.

The distances from Top-Mid Mask to Mid-Nosebridge, and Min Left to Left Alare are 50%-59% smaller for the males wearing the MW mask than for the male wearing the LW size.

Several distances are 20%-29% larger for the males wearing the MW mask than for the male wearing the LW size. They are: Upper Right Rivet to Glabella, Upper Right Rivet to Pronasale, Upper Left Rivet to Glabella, Upper Left Rivet to Sellion, Upper Right Pentagon to Mid-Nosebridge, Upper Right Pentagon to Pronasale, Upper Left Pentagon to Mid-Nosebridge, Upper Left Pentagon to Pronasale, Lower Right Pentagon to Pronasale, Min Right to Glabella, Min Left to Sellion, Min Left to Left InfraOrbitale, Max Right to Right Tygion, Max Right to Right InfraOrbitale, and Right Zygion to Right InfraMalar.

The distances from Upper Right Rivet to Sellion, and Min Right to Sellion are 30%-39% larger for the males wearing the MW mask than for the male wearing the LW size.

The distances from Upper Left Pivet to Mid-Nosebridge, Top-Mid Mask to Sellion, and Max Left to Left InfraMalar are 40%-49% larger for the males wearing the MW mask than for the male wearing the LW size

The distances from Upper Right Rivet to Mid-Nosebridge, Top-Mid Mask to Glabella, Bottom-Mid Mask to Supramenton, and Max Right to Right InfraMalar are 50%-59% larger for the males wearing the MW mask than for the male wearing the LW size.

Variation Affecting Overall Score Within a Size

Males in SN

All significant differences found were non-anthropometric. The distance from Top-Mid Mask to Mid-Nosebridge is 20%-29% larger for the good fits over the bad fits. The distance from Bottom-Mid Mask to Promenton is 30%-39% larger for good fits over the bad fits. That means the men in SN who have good fits are wearing their masks differently on their faces than the men in SN who have poor fits.

Males in MN

There was only one significant difference between good fits and bad fits for males in size MN. It was the distance from Bottom-Mid Mask to Promenton which was 19.5% larger for the men with good fits in MN over the poor fits. Again, this was not an anthropometric difference. This means the men in MN who have good fits are wearing their masks differently on their faces than the men in MN who have poor fits.

Males in MW

While there were many significant differences found between the males in size MW with good fits and those with poor fits, only one was anthropometric. That one significant anthropometric difference was the distance from Promenton to Supramenton which was 20%-29% smaller for the good fits over the poor fits. It is possible that this is important. However, only one subject received a poor fit because of lack of comfort in the chin region, and he should have been in the LW size by the T.O. criteria. More importantly, the large number of non-anthropometric

differences shows that the men in MW with good fits are wearing their masks differently on their faces than the men in MW with poor fits. All significant differences include non-anthropometric differences follow.

The distances from Lower Left Pentagon to Promenton, Bottom-Mid Mask to Promenton, and Min Right to Right Alare are 30%-39% smaller for men in MW with good fits over men in MW with poor fits.

Several distances are 20% - 29% smaller for the good fits in MW over the poor fits. They are: Upper Left Rivet to Promenton, Upper Right Pentagon point to Promenton, Upper Left Pentagon to Promenton, Upper Left Pentagon to Supramenton, Lower Right Pentagon to Promenton, Lower Left Pentagon to Supramenton, Top-Mid Mask to Mid-Nosebridge, Min Right to Right InfraMalar, Min Left to Left Alare, and Promenton to Supramenton.

The distances from Max Right to Right InfraMalar, and Max Left to Left InfraMalar are 20% - 29% larger for the good fits in MW over the poor fits.

Males in LW

There are only 2 subjects in LW; 1 with a good fit and 1 with a poor fit. Thus the variance of the data is much larger than the other sizes, yet there is still only one anthropometric significant difference at 20%-29% between the two subjects (the distance from Right InfraMalar to Right InfraOrbitale) which is not considered to have impacted the fit. All of the significant differences are listed below. All of the other differences combine to show that the male with a good fit wears his mask differently on his face than the male with a poor fit.

The distances from Top-Mid Mask to Glabella, and Bottom-Mid Mask to Supramenton are 50%-59% smaller for good fit in LW over the poor fit.

The distance from Top-Mid Mask to Sellion is 40%-49% smaller for the good fit in LW over the poor fit.

The distances from Upper Right Rivet to Mid-Nosebridge, Upper Left Rivet to Mid-Nosebridge, Bottom-Mid Mask to Promenton, and Mid-Nosebridge to Pronasale are smaller by 30% - 39% for the good fit in LW over the poor fit.

The distances from Upper Right Rivet to Glabella, Upper Right Rivet to Sellion, Upper Left Rivet to Sellion, Upper Right Pentagon to Mid-Nosebridge, Upper Left Pentagon to Mid-Nosebridge, Lower Left Pentagon to Supramenton, Max Right to Right InfraMalar, and Right InfraMalar to Right InfraOrbitale are smaller by 20% - 29% for the good fit in LW over the poor fit.

The distance from Top-Mid Mask to Mid-Nosebridge is larger by 30% for the good fit in LW over the poor fit.

Females in SN

Even though it is not known how valid our data are for the females in this study, the ratios for the females in size SN with good fits to poor fits were studied. The only significant distances are from Bottom-Mid Mask to Promenton, and Min Left to Left InfraOrbitale which are 20%-29% larger for the good fits over the poor fits for females in mask size SN.

This shows that the females in the SN with good fits are wearing their masks differently on their faces than the women in SN with poor fits.

NOTE: The masks are also rotated slightly to the right. Possible explanation: Systematically tightening the mask to the helmet in one direction; or possibly the helmet is too loose allowing the mask to slip on the face.
